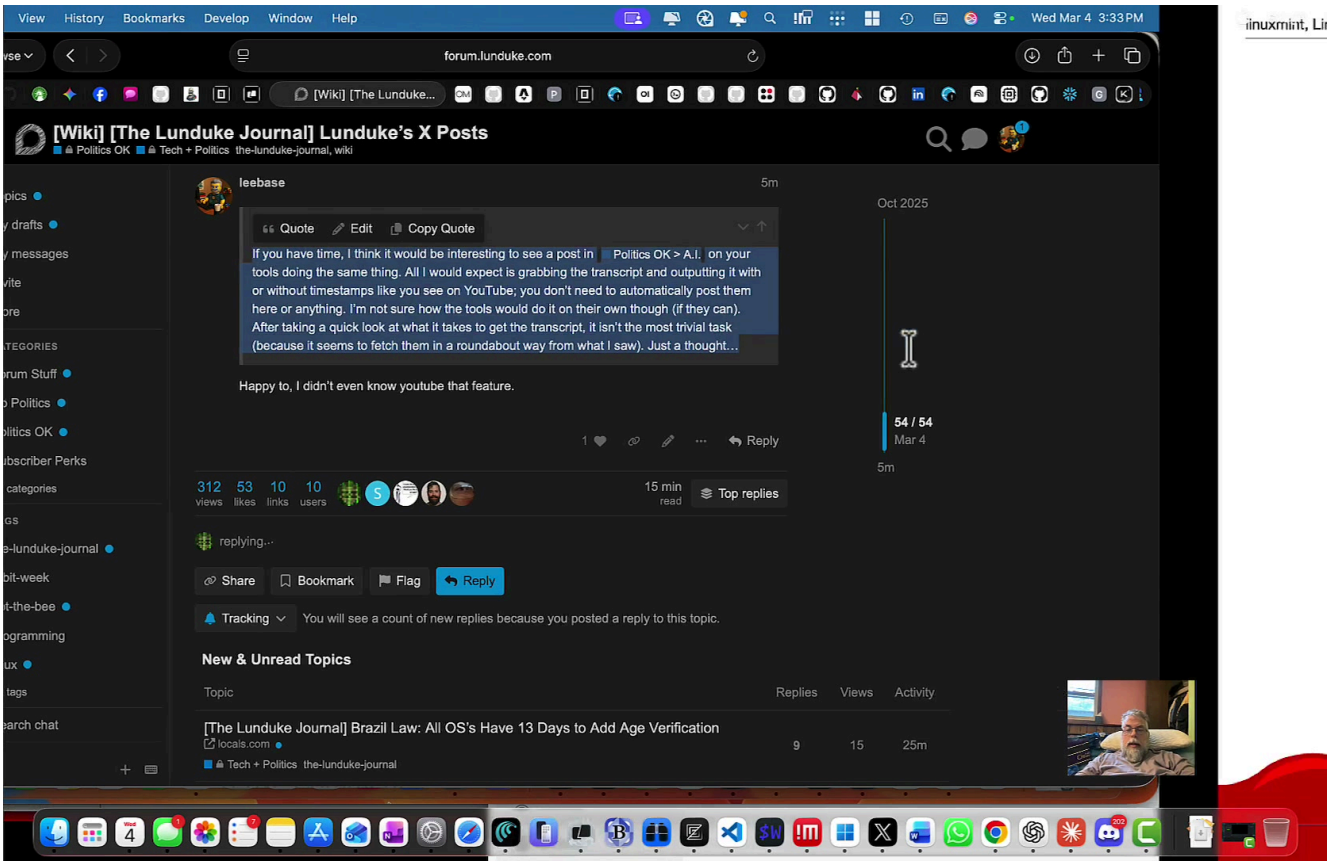
Starting a New Codec Project and Organizing Files

Step 1: Access the Remote Mac Mini

Begin by remotely logging into your Mac Mini to set up your working environment. This prepares your system for project creation and management.

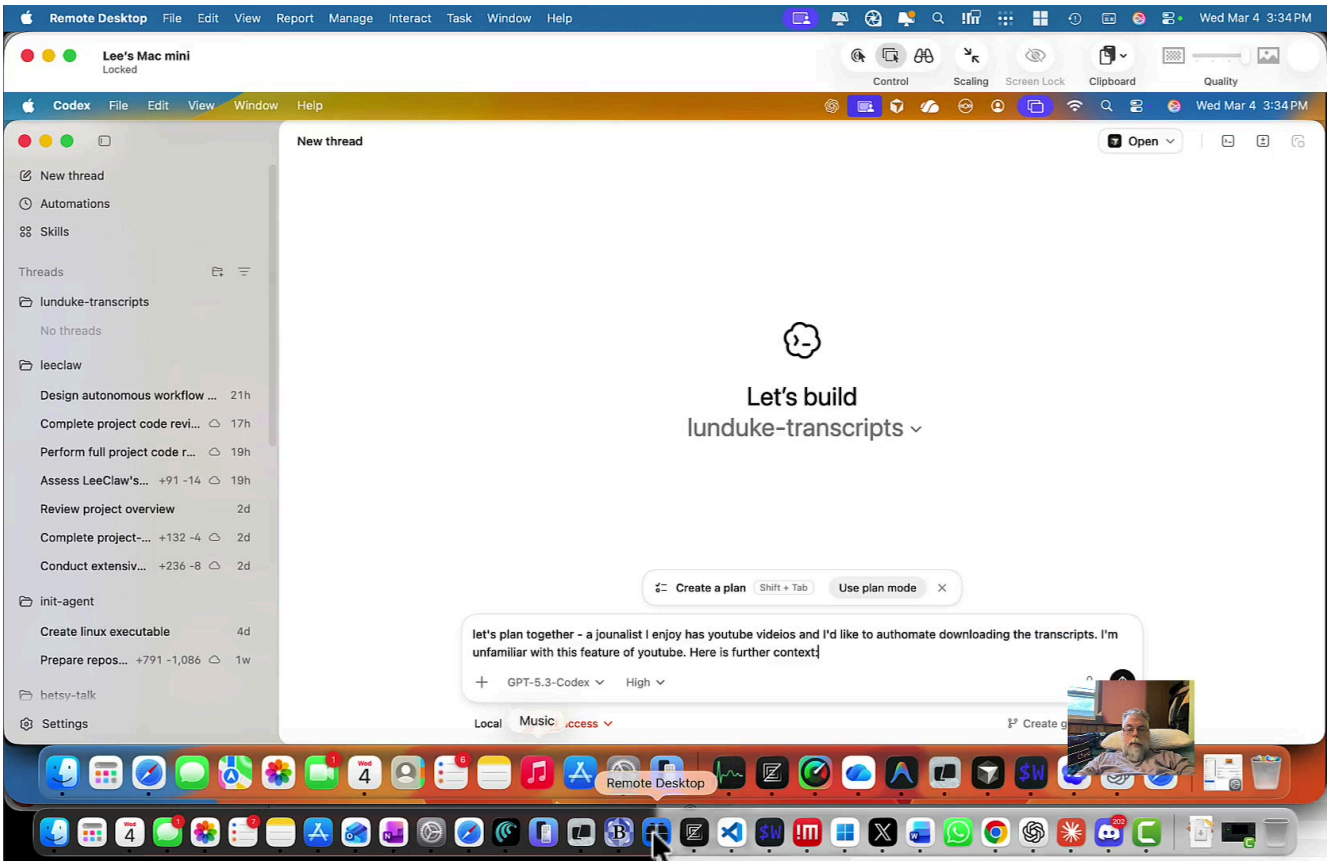
> **Evidence:** The speaker states, "I am remoted into my Mac Mini."



Step 2: Create and Name Your Project Folder

Create a new folder for your project using Finder or your preferred MacOS file manager. Name the folder appropriately to reflect your project's purpose. For example, you might name it `Lunduke Transcript`.

> **Evidence:** The speaker shares, "I'm going to call it the Lunduke Transcript, so I've already created the folder."

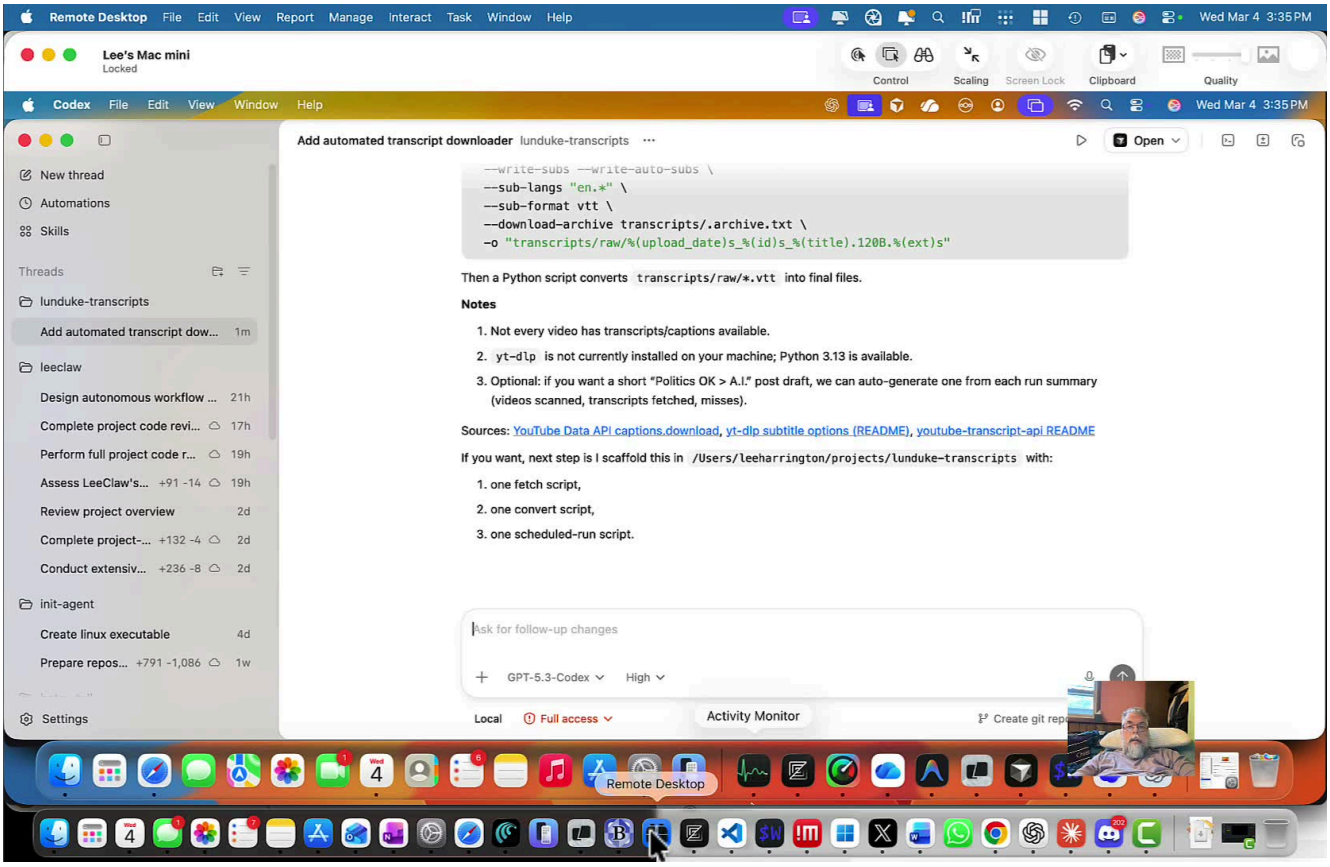


Planning the Project with AI Collaboration

Step 3: Engage the AI as a Collaborative Co-Thinking Partner

Kick off your project planning by interacting with AI as a co-thinker or brainstorming partner. Use GPT 5.3 codecs through ChatGPT Plus to help explore ideas and organize your thoughts.

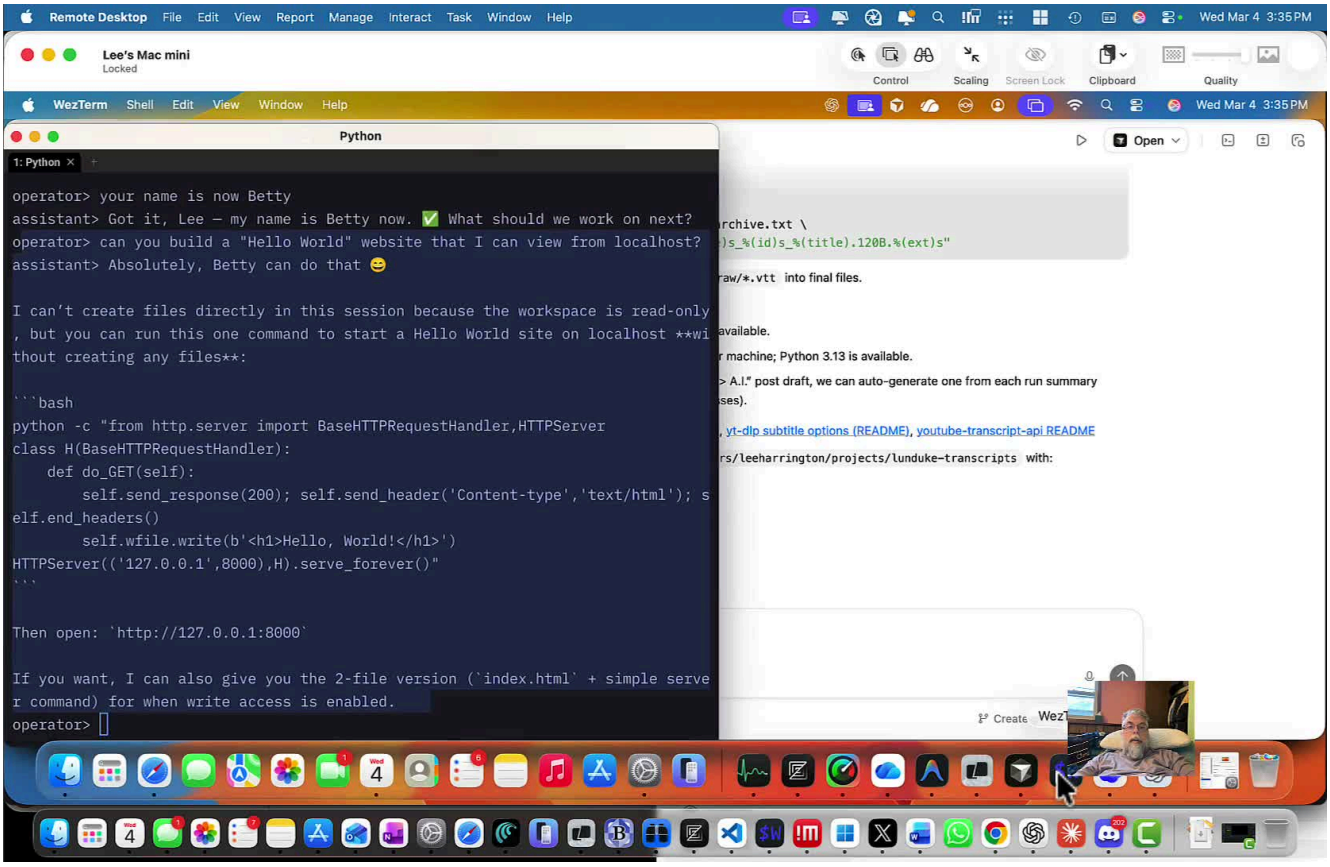
> **Evidence:** The speaker explains, "So I always start my projects engaging the AI as a co-mind, a co-thinker... I'm using GPT 5.3 codecs through my chat GPT plus subscription."



Step 4: Define the Project's Product Definition and Goals

Collaborate with the AI to articulate clear goals and deliverables for your project. This includes setting a product definition that outlines what you want the project to achieve, such as automatically fetching YouTube video transcripts.

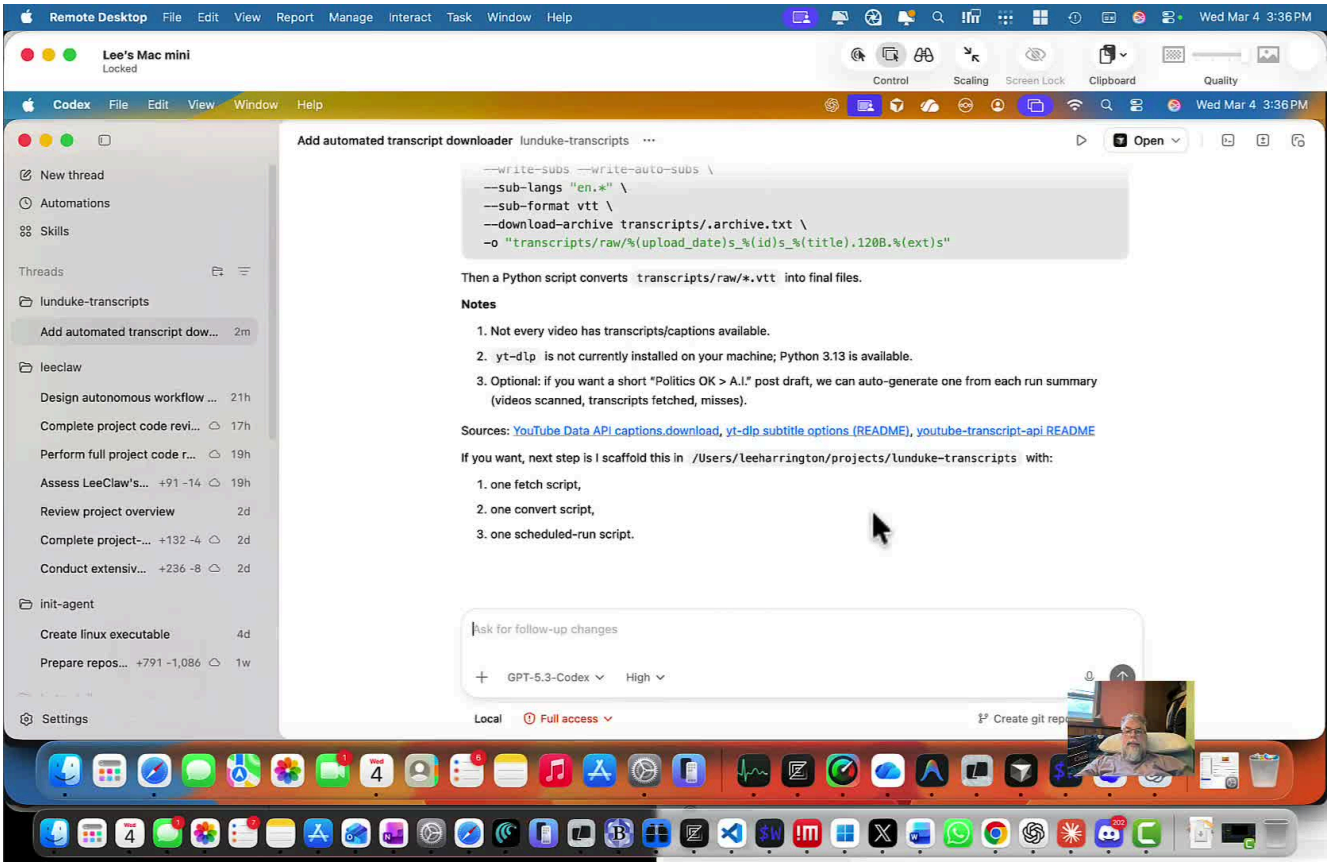
> **Evidence:** The speaker discusses, "So that does the lead work through here, project, definition... This is the goal... Yeah, this is a good list of things we want done."



Step 5: Create the Design for the Project

With the AI's assistance, design the architecture and choose your technology stack. For this project, the recommended stack includes Python for data modeling and SQLite for the datastore. You might also use terminal tools like Warp to manage dependencies and installation.

> **Evidence:** The speaker notes, "And the next step is create a design... Python, YT, okay, data modeling, validation, SQLite... Because codecs can actually do this install... I would use warp, the warp terminal."

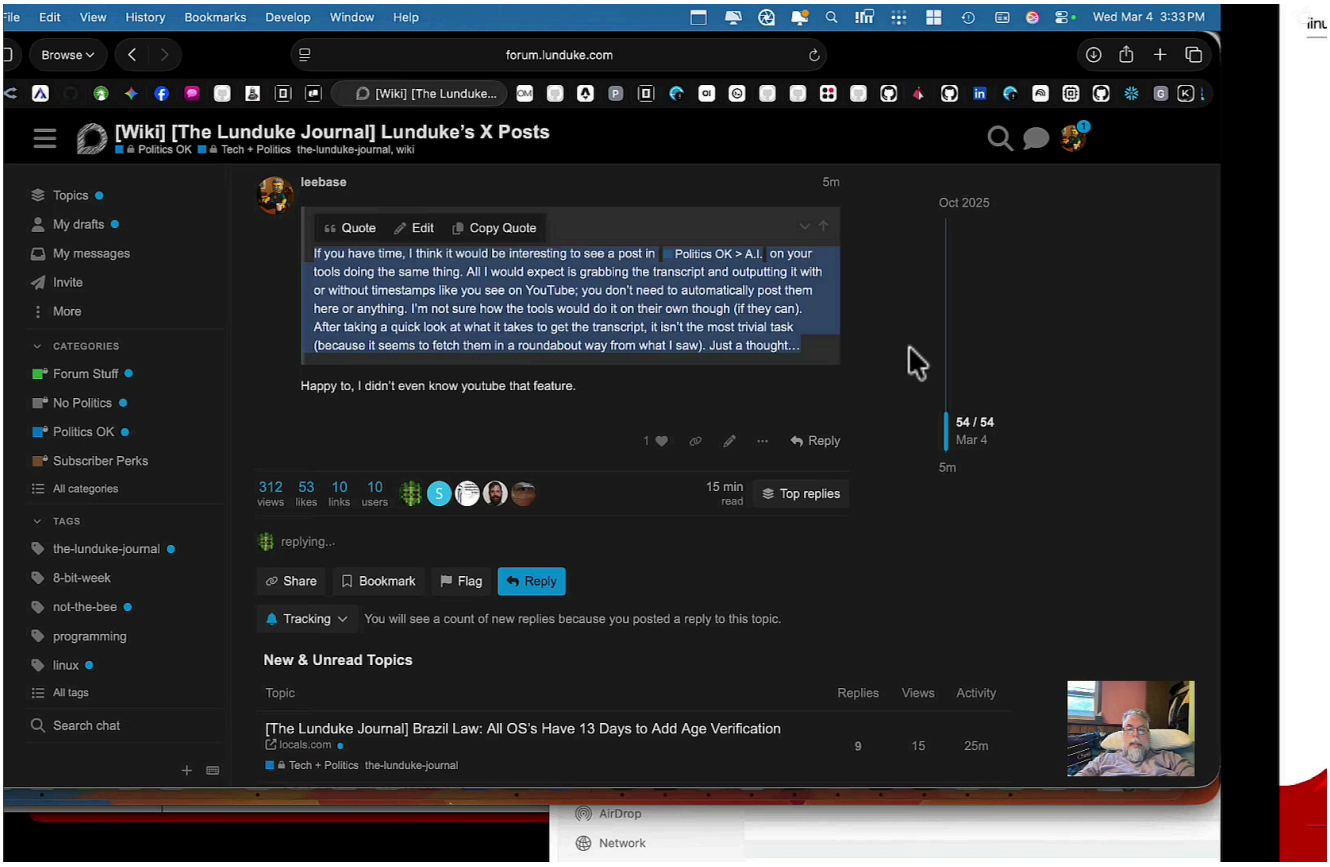


Downloading and Using YouTube Video Transcripts

Step 6: Locate and Download YouTube Video Transcripts

Identify YouTube videos that relate to your project and download their transcripts. YouTube provides raw transcript text that can serve as a data source for your project.

> **Evidence:** The speaker mentions, "I don't even need to tell him this, but I am, has YouTube videos and I'd download the transcripts... this is what YouTube gives you..."



Step 7: Integrate Transcripts into the Project

Leverage AI to convert raw YouTube transcripts into reader-friendly format. This includes processing the text into structured articles featuring titles, paragraphs, timestamps, and metadata. You can run this on specific time frames or process all new transcripts automatically.

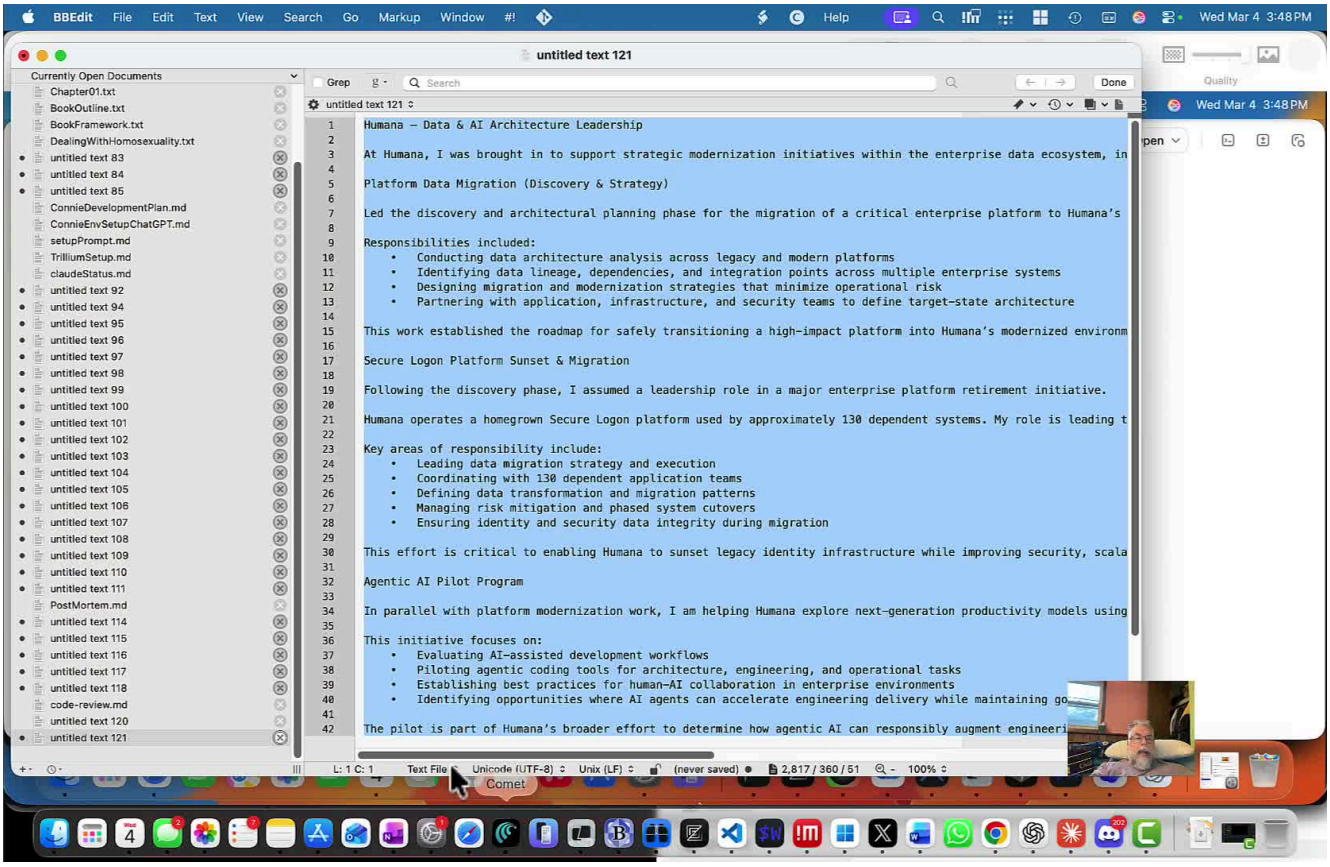
> **Evidence:** The speaker demonstrates, "Then it creates the article format, here's a title, here's paragraphs... at the end of the paragraphs it gives you the timestamp... you can run it for a time frame, or you could just run it, and it will get anything that's new."

Executing the Project Using Agent Flow Methodology

Step 8: Initialize the Agent and Load Project Data

Open your codec environment terminal on the Mac and run the `init agent` command. This loads the project's metadata, planning documentation, and any pre-defined sprint tasks to prepare for development.

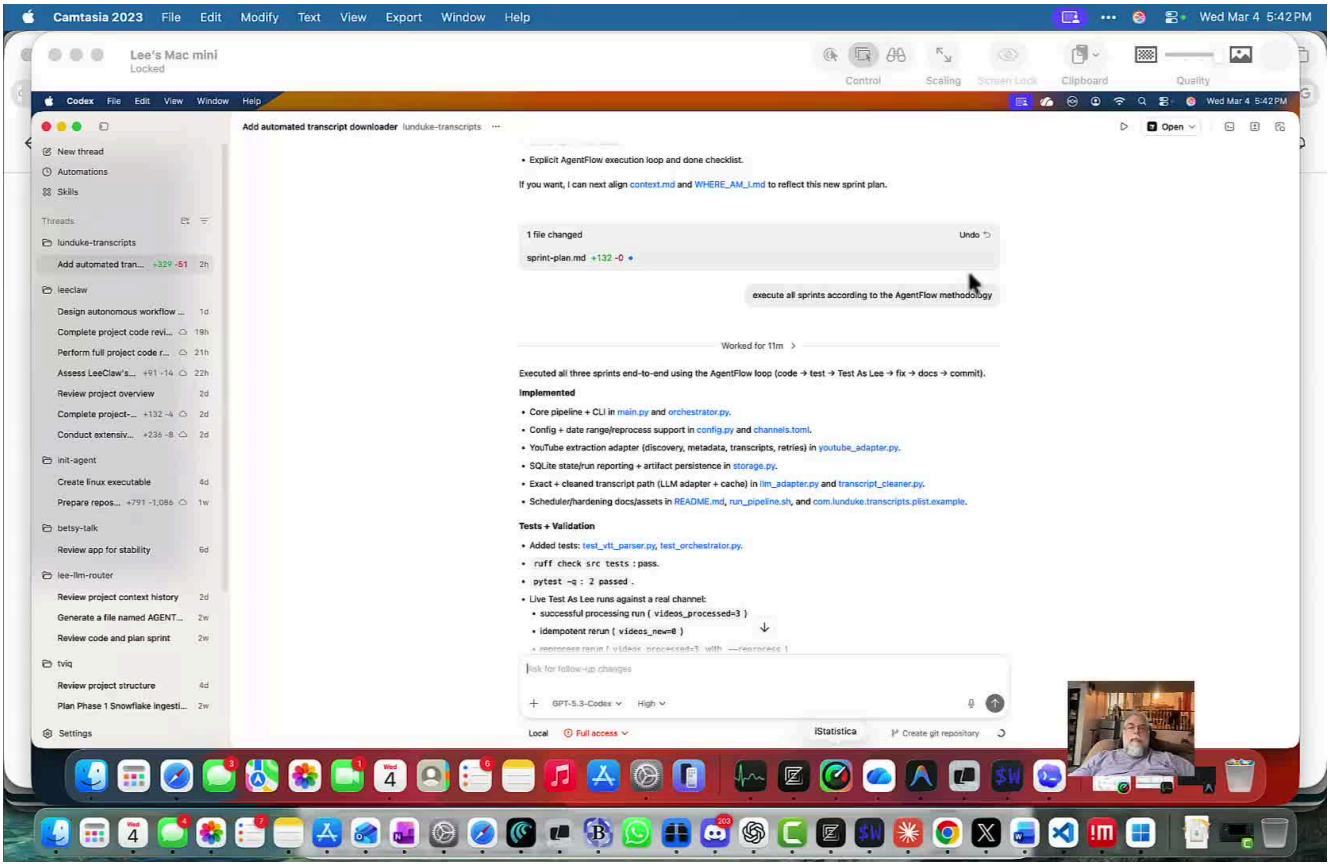
> **Evidence:** The speaker shows, "Let me come over here, and let me do init agent... now if I go to Lunduke, see now I have the agent's metadata, the agent's markdown, project plan, all that stuff is preloaded."



Step 9: Create and Execute a Sprint Plan

Work with the AI to break down your project tasks into short, testable sprints. After planning, command the AI to execute all planned sprints sequentially, following the agent flow methodology.

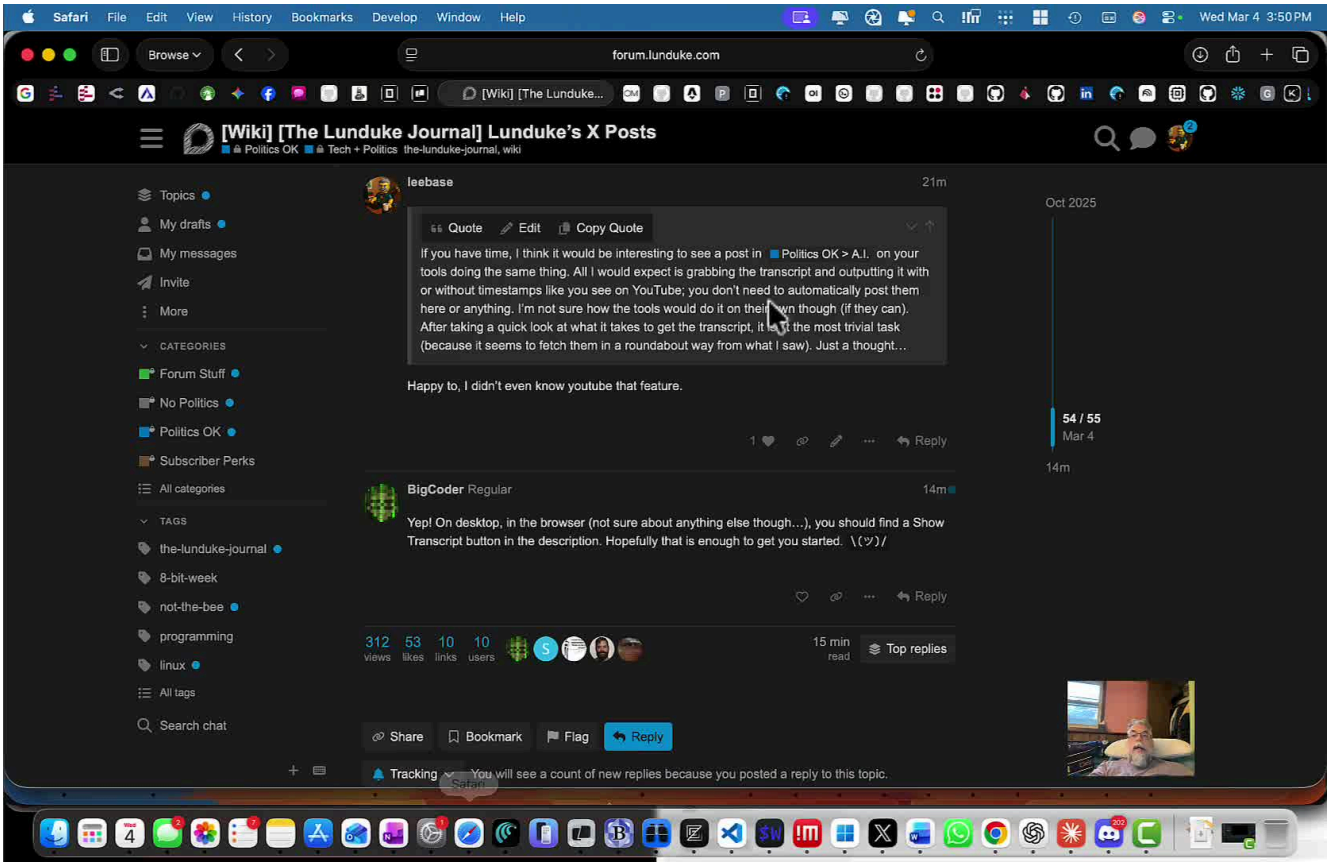
> **Evidence:** The speaker explains, "Okay, now create a sprint plan... So a sprint plan breaks the accomplishment of the task into small, testable pieces... execute all sprints according to the agent flow."



Step 10: Perform Code Testing, Debugging, and Documentation Updates

After sprint execution, test your code both as a developer and as an end-user. Use AI's assistance to identify and fix bugs. Update project documentation, including your progress tracker document known as “where am I,” to keep your project status clear.

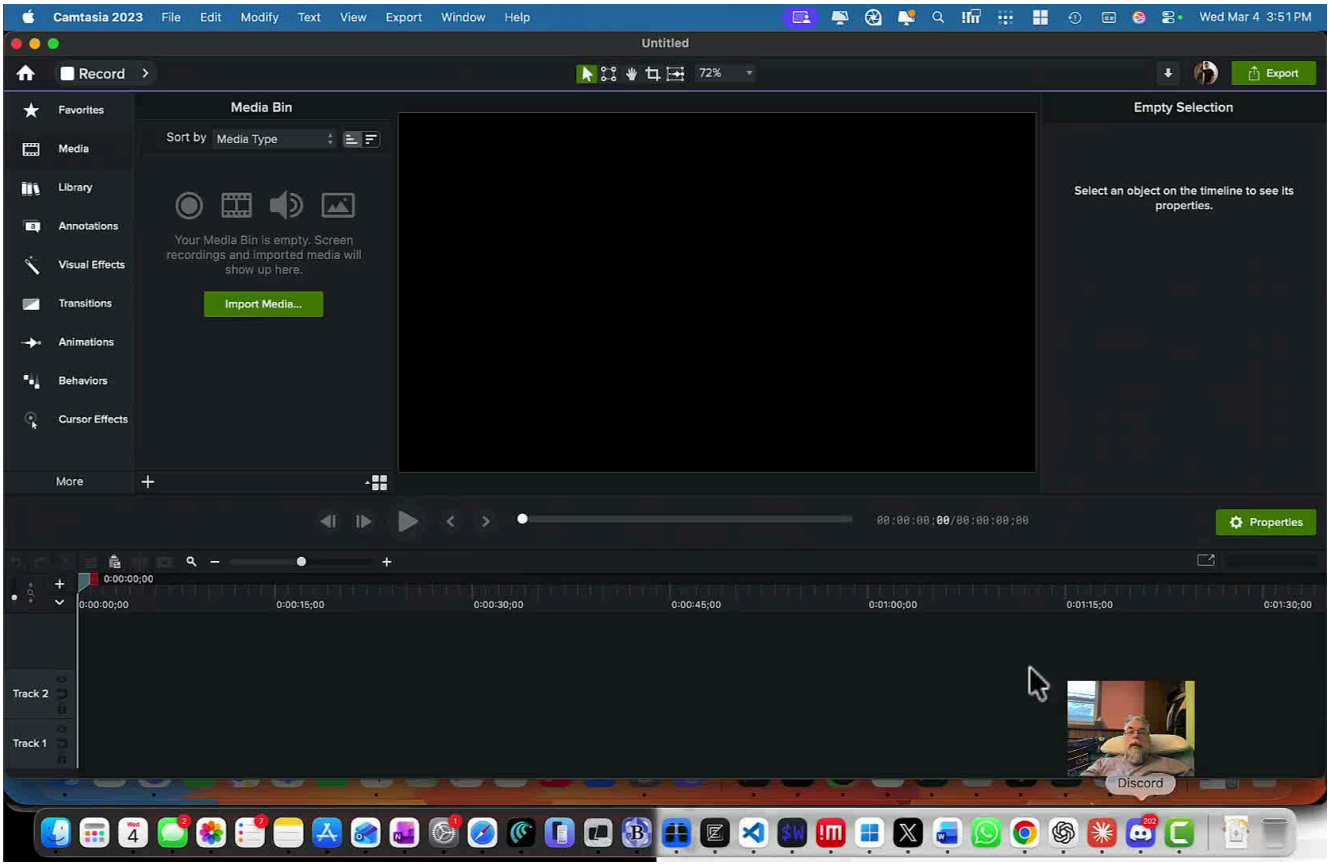
> **Evidence:** The speaker notes, "You code, you test, you fix your own bugs, then you test as user, test as me... including what I call is where am I... This will tell me where I'm at in the project."



Step 11: Conduct Comprehensive Code Review

Use AI tools to perform detailed code reviews covering formatting, security, performance, scalability, and maintainability. Review findings guide additional sprints and iterative improvements.

> **Evidence:** The speaker describes, "I have a review process... check for format, run the linter, type check, tests, dependency vulnerability... security review... performance and scalability... overall health score... I'll feed it back into the AI... do a couple rounds of that."



By following these steps, you will be able to start a new codec project, engage AI for collaborative planning, incorporate YouTube transcripts, and efficiently execute and review your project using the agent flow methodology.
